

The specificities of several other methods for raising an antibody against an expressed protein with a foreign antigen are described. One method, developed at least once by immunizing thioether-linked target proteins and at least one target peptide having a specific antigenic determinant, and linking the target peptide to the target protein. The method addresses production of semi-synthetic fusion proteins in vitro and is particularly useful in the production of cytotoxic T-lymphocyte (CTL) epitopes, such as those derived from endogenous peptides which have not been defined by routine methods. The isolation methods expand the ability to incorporate non-coded amino acids into target proteins. Subsequent to preparation of a library of target peptides, it is most suitable to raise monoclonal antibodies against individual peptides and specific determinants and to identify those few in vitro expressed proteins isolated using a modified screening technique. The foreign sequence represents a fusogenic insert in the course of the thioether.
